

Browser Forensics Analysis Using Hindsight

Student: Jobayer Bhuiyan

Course: Network Forensics

Instructor: Chris Lewis

Date: March 2026

Abstract

This report examines Google Chrome browser artifacts parsed with Hindsight in order to reconstruct user activity and assess possible anti-forensic behavior. The analysis focuses on the Hindsight timeline output, profile-based filtering, search activity, Google Drive access, download history, and email-related entries visible in the provided screenshots. The evidence shows a sequence in which browser activity was narrowed to a specific profile, a search for 'sdelete download' was identified, a download of SDelete.zip was observed, and Google Drive activity appeared in the surrounding timeline. Because SDelete is a secure deletion utility designed to overwrite data so that recovery is more difficult, its presence is significant in a forensic context. The report distinguishes clearly between what the artifacts directly show and what can reasonably be inferred from their timing and relationship within the browser timeline.

Introduction

Browser forensics is valuable because modern web browsers preserve a large amount of evidence about what a user searched for, viewed, downloaded, and attempted to access. Even when files are later removed from a system, browser artifacts can still reveal user intent, sequence of actions, and possible efforts to hide activity. Hindsight is especially useful in this type of examination because it parses Chrome artifacts into a structured timeline that investigators can sort, search, and filter during analysis.

The purpose of this assignment is to show how Hindsight can be used as an investigative tool to move from raw browser data to a defensible reconstruction of events. In this case, the screenshots and timeline entries support a focused review of profile usage, search behavior, Google Drive access, download activity, and email-associated entries. Together, these artifacts provide a practical example of how browser evidence can support an investigation into suspicious or potentially concealed user behavior.

Methodology

The investigation began with the Hindsight Excel output for Google Chrome. The Timeline sheet was used as the primary evidence source because it consolidates multiple browser artifacts into one reviewable chronology. Based on the screenshots, the examiner reviewed key columns such as Title / Name / Status, URL or Data / Value / Path, Interpretation, Profile, Source, and Timestamp or Duration fields when present. Rather than relying on a general summary, the analysis was performed through repeated filtering of the timeline to isolate actions most relevant to user behavior.

Three filtering steps were especially important. First, profile filtering was used to separate activity associated with Default, Profile 1, and Profile 2. Second, source filtering was applied to emphasize local artifacts and reduce noise from less useful entries. Third, text filters such as 'contains' were used to locate keywords, including 'email,' so that identity-related or credential-related artifacts could be examined more efficiently. Timestamps visible in the timeline were interpreted comparatively, meaning the report focuses on the observable order and proximity of events shown in the provided evidence.

Profile Identification and Scope

The screenshots indicate that the browser data included at least three profiles: Default, Profile 1, and Profile 2. This is an important forensic detail because multiple Chrome profiles may represent different users, different usage contexts, or deliberate separation of activity on the same system. Figure 1 shows the profile filter being opened and the Default profile being isolated. This confirms that the examiner did not treat the browser history as a single undifferentiated dataset.

Findings and Analysis

1. Search activity suggesting intent

Figure 2 shows a timeline entry for the query 'sdelete download.' The Interpretation column states that the user searched for the phrase after typing it before clicking on a suggestion, which is an important point because it indicates manual input rather than passive browsing. In a forensic analysis, a manually typed search is stronger evidence of user intent than a background process or auto-generated request. The screenshot also places that entry within the broader Chrome timeline, allowing it to be evaluated alongside nearby Google and Google Drive activity.

2. Download of a secure deletion utility

Figure 3 highlights a subsequent entry showing the download of SDelete.zip. This observation is a fact directly supported by the timeline. Its significance comes from what SDelete is: a Microsoft Sysinternals utility commonly used to securely delete data by

overwriting file contents so that recovery is harder. In a digital investigation, downloading such a tool can be relevant because it may indicate preparation for evidence destruction or concealment. However, the correct forensic position is that the download itself demonstrates access to the tool, not definitive proof that the tool was used on specific files.

3. Google Drive activity in the same event sequence

Figures 2 and 3 both show Google Drive and My Drive entries near the suspicious search and download activity. This timeline relationship matters because cloud storage access before or around a deletion tool download can support an inference that files may have been viewed, staged, transferred, or prepared for removal. That said, the browser artifacts alone do not prove that files were uploaded or deleted. The more defensible conclusion is that Google Drive activity was temporally associated with the SDelete-related behavior, making it a relevant lead for deeper examination.

4. Reduction of noise through source filtering

Figure 4 shows the Source filter menu and the selection process used to narrow the timeline to the most useful entries. This matters methodologically because a reproducible forensic process depends on showing how irrelevant noise was reduced. Instead of simply stating that the timeline was reviewed, the screenshot demonstrates that local entries were deliberately emphasized. That makes the analysis more transparent and helps explain why the suspicious events stand out more clearly in the report.

5. Extraction of identity-related artifacts

Figures 6, 7, and 8 document the process of locating email-related evidence. Figure 6 shows the use of a text filter on the Title / Name / Status field. Figure 7 shows the custom autofilter configured to search for entries containing the keyword 'email.' Figure 8 then displays the resulting entries, including addresses such as fred.rocba@gmail.com and frocba@stark-research-labs.com. These entries are important because they may help connect browser activity to an account, login attempt, saved credential artifact, or a particular user context. Still, the safest conclusion is that the email addresses were present in relevant browser records; additional corroboration would be needed before attributing all suspicious activity to one person with certainty.

Attribution and Interpretation Limits

The presence of multiple browser profiles means attribution must be handled carefully. The report can state with confidence that suspicious events were observable within filtered profile-based timeline views, but it should avoid claiming more than the screenshots prove. A browser profile can suggest a specific user context, but it is not identical to verified human identity. Likewise, the combination of the search query, Google Drive access, and SDelete.zip

download is suspicious and consistent with possible concealment behavior, yet it remains an inference based on timeline correlation rather than direct proof of file destruction.

This distinction between fact and interpretation is central to forensic writing. The observable facts include the search query, the download entry, the nearby Google Drive activity, the filtered source views, and the email-related timeline results. The interpretation is that these events, taken together, suggest deliberate planning and possible anti-forensic intent. That interpretation is reasonable, but it should be presented as an analytical conclusion supported by the timeline, not as an absolute statement that evidence was destroyed.

Conclusion

The Hindsight output provided a clear way to reconstruct a meaningful sequence of browser activity. After narrowing the dataset by profile and source, the timeline revealed a manually typed search for 'sdelete download,' nearby Google Drive activity, and a later download of SDelete.zip. Additional filtering exposed email-related entries that may assist with attribution. Taken together, these artifacts demonstrate how browser forensics can move beyond simple history review and help an investigator identify intent, sequence, and potentially concealed behavior. The strongest forensic conclusion is not that deletion definitely occurred, but that the browser evidence supports a well-grounded suspicion of preparation for concealment and provides a strong basis for further system and cloud-based examination.

Text filter menu showing the use of a 'contains' search on the timeline data. This documents the method used to locate targeted evidence instead of manually scanning the entire spreadsheet.

Figure 7

Custom AUTOFILTER

Show rows where:

Title / Name / Status

contains email

And Or

Use ? to represent any single character
Use * to represent any series of characters

OK Cancel

Figure 8

Custom autofilter configured with the keyword 'email.' This shows the exact filter condition applied before the resulting artifacts were reviewed.
